

# Pi SZ Alpha 1 Antitrypsin Deficiency and other rarer types

An information leaflet for patients and families

**Building healthier lives**

**UHB is a no smoking Trust**

To see all of our current patient information leaflets please visit  
[www.uhb.nhs.uk/patient-information-leaflets.htm](http://www.uhb.nhs.uk/patient-information-leaflets.htm)

## Introduction

This leaflet is written for people with alpha 1 antitrypsin deficiency ( $\alpha$ 1AD) of the Pi SZ type.

## What is $\alpha$ 1 antitrypsin ( $\alpha$ 1AT)?

$\alpha$ 1AT is a chemical made in the liver that circulates in your bloodstream.

## What is $\alpha$ 1AD?

Individuals with  $\alpha$ 1AD have very low levels of  $\alpha$ 1AT in their bloodstream. Individuals with PiSZ  $\alpha$ 1AT also have low levels of  $\alpha$ 1AT in their blood, but not as low as people with two Z genes.

## Why is $\alpha$ 1AT important?

$\alpha$ 1AT protects lung tissue from an enzyme (elastase) released by white blood cells. Elastase fights infection in the lungs. However if not tightly controlled by  $\alpha$ 1AT, elastase can attack healthy lung tissue.

## What causes $\alpha$ 1AD?

Our ability to make  $\alpha$ 1AT is inherited through genes passed on by both parents. One of these genes is known as Protease Inhibitor (Pi). It is this gene that makes the  $\alpha$ 1AT.

## How is it inherited?

We all have two Pi genes. We inherited one gene from our mother and the other gene from our father. When a couple has a child they each pass on one of their Pi genes.

## What are the different genetic types?

There are more than 100 different variants of the Pi gene. Most variants result in normal levels of  $\alpha$ 1AT in the blood, but some result in reduced levels or no  $\alpha$ 1AT. The most common variants are called M, S and Z.

Most people have two copies of type M variant (written as PiMM) and have normal levels of  $\alpha$ 1AT in the bloodstream.

### Pi SZ

Type Z results in low levels of  $\alpha$ 1AT in the bloodstream. Type S results in slightly low levels. Someone with PiSZ has a low level.

## How common is $\alpha$ 1AD?

Around 1 in 2500 people in the UK have  $\alpha$ 1AD.

Most people with  $\alpha$ 1AD have two Z variants (PiZZ).

Around 1 in 10 people are carriers for the S or Z variant (4% (1 in 25) of Northern European population carry Z and 6% (1 in 17) carry S). Other types (I, F, Mmalton) are ever rarer.

## What are the effects of having $\alpha$ 1AD?

The effects of the deficiency are varied: some people remain entirely healthy.

**Lung disease:** People who smoke and have PiSZ AAT deficiency may have an increased risk of developing lung problems such as emphysema (although this still remains uncertain). Non-smokers are not believed to be at a greater risk than normal of lung disease.

If lung disease is present symptoms include shortness of breath, wheezing and recurrent chest infections. It is recommended that everyone in the UK with Chronic Obstructive Pulmonary Disease (COPD) is tested for  $\alpha$ 1AD.

**Liver problems:**  $\alpha$ 1AT is made in the liver. In PiSZ patients, the  $\alpha$ 1AT accumulates in the liver and can cause problems, however most people do not develop serious liver problems.

Pi SZ AAT deficiency is not thought to be associated with liver health problems.

## What can people with PiSZ $\alpha$ 1AT do to look after their health?

1. Avoid smoking and passive smoking. Smoking attracts white blood cells to the lungs, and speeds up the development of lung disease. Other lung irritants e.g. dust particles and air pollution
2. Be referred to a specialist centre for  $\alpha$ 1AD for regular monitoring. See your GP for early treatment of lung infections or breathing problems or if you are concerned about any symptoms mentioned in this leaflet.
3. Drink alcohol only in moderation and exercise regularly.

## Other Pi variants

Some people inherit rarer AAT genes such as Mmalton, I or F. There is less information available about these genes.

Mmalton AAT has a tendency to accumulate in the liver (it forms "polymers") and therefore can be associated with liver disease. If Mmalton is inherited with a Z gene (PiMmaltonZ) there is an increased risk of developing lung problems such as emphysema just like ZZ. For this reason it is very important to give up smoking if you have PiMmaltonZ AAT deficiency.

People who inherit both an I and Z gene (PiIZ) appear to be at increased risk of liver and lung disease compared to healthy people, there is not much information available at present about I AAT. However, it is still safer not to smoke if you have PiIZ AAT deficiency.

F AAT can be associated with normal levels of AAT in the blood, but this particular type of AAT does not work as well as normal AAT. People who inherit both F and Z genes (Pi FZ) also seem to be at an

increased risk of getting lung problems such as emphysema. Again, it is important not to smoke if you have Pi FZ AAT deficiency.

## Further information

### Alpha-1 UK Support Group

36 Cecil Avenue, Lipson, Plymouth. PL4 8SG
